

SODA

Solana-Owned Derived Authority

Your Solana account owns an address on every other chain.

Native assets · Native addresses · No bridge

Every new chain is an exit from Solana.

FOR USERS

1 Users leave to reach new apps.

A new chain means a new wallet, and the Solana session ends.

2 Solana apps lose the relationship.

Once users are elsewhere, they have fewer reasons to come back.

3 Solana's reach stops at its own boundary.

Users should explore other ecosystems from the account they already have.

FOR INSTITUTIONS

1 The capital is on Solana. The yield is not.

Ethereum holds \$17.2B of tokenized RWA against Solana's \$4.1B.

2 Bridges are not investable.

No treasury committee signs off on infrastructure whose failure mode is a nine-figure hack.

3 A private key has no segregation of duties.

Whoever holds it can do anything. Policy sits in a vendor dashboard, and auditors are asked to take it on trust.

4 Every new chain is another custody relationship.

Another key, another provider, another audit, another counterparty.

\$2.8B+

stolen from bridges since 2022

69%

of all DeFi funds ever stolen — bridges

Ronin \$624M · Wormhole \$326M · Nomad \$190M

Make Solana the only chain anyone needs.

HOW IT WORKS

Your Solana account deterministically owns an address on every other chain — the Solana program decides what may be signed, and Solana verifies the signature on-chain before it is ever broadcast.

Solana program authorizes → MCP committee signs → Solana verifies → executes on the target chain

Solana as the home account

Authorize transactions on other chains from the account users already have.

More capability inside Solana apps

Perps, tokenized RWAs and lending markets, reached from a Solana app.

Infrastructure any chain can adopt

An intent layer wallets and apps across ecosystems can integrate.

Native assets. Native addresses. No wrapped tokens, no pooled bridge contract.

Use any chain's DeFi with nothing but a Solana wallet.

No second wallet. No second gas token. No bridging. A Solana program authorizes, Solana verifies, the other chain executes.

[LENDING & YIELD]

Earn on idle assets

Supply collateral, borrow against it, hold an interest-bearing position.

e.g. Aave · Morpho · Compound

[DERIVATIVES]

Hedge and take leverage

Open and manage perpetual positions from a Solana app.

e.g. Hyperliquid · GMX

[TOKENIZED ASSETS]

Hold real-world assets

Treasuries, money-market funds and tokenized equities, settled on the chain that issues them.

e.g. BUIDL · Ondo · Franklin Templeton

[NATIVE HOLDINGS]

Own the real asset

Hold native ETH or BTC at a native address — no wrapped tokens, no custodian.

e.g. any supported chain

And one thing no private key can do:

Mandates enforced on-chain

Spending caps, counterparty allowlists and time windows live in a Solana program — auditors verify the policy themselves, on a public ledger.

Agents that cannot go rogue

The agent holds nothing; the program decides what may be signed.

NEAR proved the demand. Solana has the market.

BELONGS ON SOLANA

Stablecoins **\$11B** vs \$245M **45x**

DEX volume **\$7B/day** vs \$77M/day **90x**

\$1.45B into Solana ETFs · \$1B+ Bitwise staking ETF AUM

Open USD — 140+ members incl. Visa, Mastercard, BlackRock — chose Solana

Same primitive. 45–90x the liquidity. Nobody has built it for Solana.

PROVEN ON NEAR

NEAR Chain Signatures → NEAR Intents

\$5B Nov 2025

\$10B Jan 2026

\$20B+ Jun 2026 doubling every ~5 months

25M+ swaps · \$2–3.6B monthly volume

Protocol revenue buys back \$NEAR since Feb 2026

Integrating partners earn a 50/50 revenue share

Already integrated

Ledger · LI.FI · Infonex · Kyber

LI.FI alone routes \$30B+ across 600 partners.

How it earns, and what ships next.

BUSINESS MODEL

1 Infrastructure for Solana protocols

Wallets, exchanges and apps integrate SODA to reach other chains.

2 Institutional deployments

Treasuries and asset managers who need the mandate enforced on-chain and the audit trail public.

3 Fees on completed cross-chain actions

Priced per action, shared with the app that brought the flow — the same revenue-share shape that took NEAR Intents to \$20B.

4 Value back to Solana

Solana apps stay the front door; cross-chain activity flows back in.

NEXT 3 MONTHS

MONTH 1

Threshold committee

Signing split across independent operators, so no single party can move funds.

MONTH 2

SDK and hosted endpoint

A few lines to integrate. First design partner live.

MONTH 3

Intent layer

One call, any supported chain — the layer wallets and apps plug into.

Ethereum, Base, Sui and Hyperliquid are all secp256k1 — the same committee serves all four. Adding a chain is a config entry, not a rewrite.

Two builders. The right team for this primitive.

Grant from NEAR Protocol

Lend and borrow on Aave with nothing but a Solana wallet.

Your Solana wallet owns an address on Base Sepolia. Deposit ETH into Aave V3 and borrow USDC against it, one Phantom approval each. No bridge, no ETH to hold, no second wallet. A Solana program commits the exact transaction and verifies the signature on-chain before anything is broadcast.

1 Connect your Solana wallet

Phantom on devnet. This wallet is the owner — the Ethereum address in the next step is derived from its public key, and only it can request a signature for that address.

Select Wallet

2 Derive your Ethereum address

Compute the Base Sepolia address that your Solana wallet owns. The soda program derives the same value on-chain from whoever signs, so the caller can never name an address it does not control.

Derive address

3 Use Aave V3 on Base Sepolia

Each action is one Phantom approval. The Solana program commits the exact EVM transaction, the sponsor signs it, and the sponsor's browser checks the signature on-chain before it is broadcast. Gas is topped up automatically from the sponsor key.

Deposit ETH

Aave V3 - WrappedTokenGatewayV3.depositETH

Supplies 0.0001 ETH. The derived address receives aWETH — a lending position held by a Solana account, earning interest from the next block.

Borrow USDC

Aave V3 - Pool.borrow

Borrows 0.10 USDC at the current rate against the aWETH collateral. Only the pool's owner can do this, and the derived address ends up holding an asset it never had.
